A Severe encephalitis with an uncontrolled seizure may produce impairment in a variety of cognitive functions. The appropriate treatment for cognitive impairment post-encephalitis are currently unknown. We are reporting a case of depression and cognitive impairment post-encephalitis with an uncontrolled seizure. Our case presented with global cognitive impairment and severe depression. The patient showed improvement following pharmacological treatments coupled with cognitive stimulation, and family education. The combination of multimodal treatments are needed following encephalitis. Intensive cognitive training may serve as a potential harbor for treatment of cognitive impairment post-encephalitis.
